# Decomposing Low-Rank and Sparse Matrices (Principal Component Pursuit)

- 1 Problem and Motivating Example
- 2 Principal Component Pursuit

"The whole is greater than the sum of the parts."

— Aristotle, Metaphysics

## Problem Formulation: Mixture of Sparse and Low-Rank

Given a large data matrix  $Y \in \mathbb{R}^{n_1 \times n_2}$  which is a superposition of two unknown matrices:

$$Y = L_o + S_o, (1)$$

where

- $L_o \in \mathbb{R}^{n_1 \times n_2}$  is a low-rank matrix;
- $S_o \in \mathbb{R}^{n_1 \times n_2}$  is a sparse matrix.

**Problem:** Can we hope to efficiently recover both  $L_o$  and  $S_o$ ?

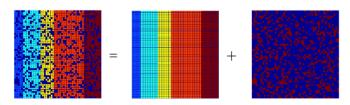

Compare this with the classic model:

$$Y = L_o + Z_o, (2)$$

where  $Z_o$  is dense but small, say Gaussian, noise?

#### PCA versus Robust PCA.

# Complexity of Low-Rank Sparse Decomposition

### Definition (Matrix Rigidity)

The *rigidity* of a matrix M (relative to rank r matrices) is defined to be:

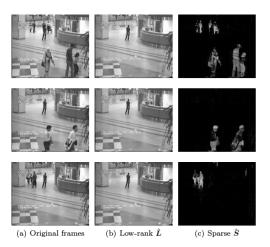

$$R_{\boldsymbol{M}}(r) \doteq \min\{\|\boldsymbol{S}\|_{0} : \operatorname{rank}(\boldsymbol{M} + \boldsymbol{S}) \le r\},\tag{3}$$

the smallest # of entries modified in order to change M rank r.

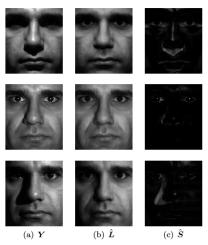

## Computing matrix rigidity is NP-Hard<sup>1</sup>, so is decomposition.

¹On the complexity of matrix rank and rigidity. Meena Mahajan and Jayalal Sarma M.N., 2007

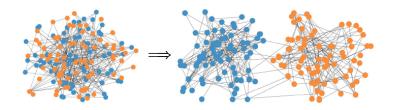

**Example.** A sequence of video frames can be modeled as a static background (low-rank) and moving foreground (sparse).

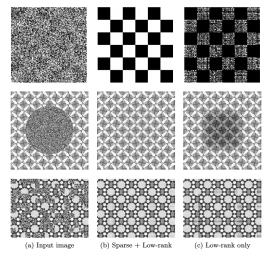

**Example.** A set of face images of the same person under different lightings can be modeled as a low-dimensional,  $3 \sim 9D$  (see Chapter 14), subspace and sparse occlusions and corruptions (specularities).

**Example.** Finding communities in a large social networks. Each community can be modeled as a clique of the social graph  $\mathcal{G}$ , hence a rank-1 block in the connectivity matrix M. Hence M is a low-rank matrix and some sparse connections across communities.

**Example.** Structured regular texture recovery (Chapter 15).

and many more...

# Convex Relaxation: Principal Component Pursuit

#### **Optimization problem:**

minimize 
$$\operatorname{rank}(\boldsymbol{L}) + \lambda \|\boldsymbol{S}\|_0$$
 subject to  $\boldsymbol{L} + \boldsymbol{S} = \boldsymbol{Y},$  (4)

which is intractable. Consider **convex relaxation**:

$$\|\mathbf{S}\|_{0} = \#\{S_{ij} \neq 0\} \rightarrow \|\mathbf{S}\|_{1} = \sum_{ij} |S_{ij}| (\ell^{1} \text{norm}).$$
 (5)

$$\mathsf{rank}(\boldsymbol{L}) = \#\{\sigma_i(\boldsymbol{L}) \neq 0\} \quad \rightarrow \quad \|\boldsymbol{L}\|_* = \sum_i \sigma_i(\boldsymbol{L}) \quad (\mathsf{nuclear\ norm}) \ (\mathbf{6})$$

#### Principal Component Pursuit (PCP):

minimize 
$$\|L\|_* + \lambda \|S\|_1$$
 subject to  $L + S = Y$ . (7)

# Alternating Directions Method of Multipliers (ADMM)

#### Augmented Lagrangian

$$\mathcal{L}_{\mu}(\boldsymbol{L}, \boldsymbol{S}, \boldsymbol{\Lambda}) = \|\boldsymbol{L}\|_{*} + \lambda \|\boldsymbol{S}\|_{1} + \langle \boldsymbol{\Lambda}, \boldsymbol{L} + \boldsymbol{S} - \boldsymbol{Y} \rangle + \frac{\mu}{2} \|\boldsymbol{L} + \boldsymbol{S} - \boldsymbol{Y}\|_{F}^{2}$$
(8)

Instead of

$$(\boldsymbol{L}_{k+1}, \boldsymbol{S}_{k+1}) = \arg\min_{\boldsymbol{L}, \boldsymbol{S}} \mathcal{L}_{\mu}(\boldsymbol{L}, \boldsymbol{S}, \boldsymbol{\Lambda}_{k}), \tag{9}$$

we realize

$$\arg\min_{\mathbf{S}} \mathcal{L}_{\mu}(\mathbf{L}, \mathbf{S}, \mathbf{\Lambda}) = \mathcal{S}_{\lambda/\mu}(\mathbf{Y} - \mathbf{L} - \mu^{-1}\mathbf{\Lambda})$$
 (10)

$$\arg\min_{\mathbf{L}} \mathcal{L}_{\mu}(\mathbf{L}, \mathbf{S}, \mathbf{\Lambda}) = \mathcal{D}_{1/\mu}(\mathbf{Y} - \mathbf{S} - \mu^{-1}\mathbf{\Lambda})$$
(11)

## Soft-thresholding operators

Recall

$$S_{\tau}(x) = \operatorname{sgn}(x) \max(|x| - \tau, 0) \tag{12}$$

For matrix  $oldsymbol{M} = oldsymbol{U} oldsymbol{\Sigma} oldsymbol{V}^*$  , we define the singular value thresholding operator

$$\mathcal{D}_{\tau}(\boldsymbol{M}) = \boldsymbol{U}\mathcal{S}_{\tau}(\boldsymbol{\Sigma})\boldsymbol{V}^*. \tag{13}$$

Dominating computation is  $\mathcal{D}_{1/\mu}$ , can speed up using partial SVD.

# Algorithm: Alternating Direction Minimization

- 1: **initialize:**  $S_0 = \Lambda_0 = 0, \mu > 0.$
- 2: while not converged do
- 3: compute  $oldsymbol{L}_{k+1} = \mathcal{D}_{1/\mu}(oldsymbol{Y} oldsymbol{S}_k \mu^{-1}oldsymbol{\Lambda}_k)$
- 4: compute  $S_{k+1} = S_{\lambda/\mu}(Y L_{k+1} \mu^{-1}\Lambda_k)$
- 5: compute  $\mathbf{\Lambda}_{k+1} = \mathbf{\Lambda}_k + \mu (\mathbf{L}_{k+1} + \mathbf{S}_{k+1} \mathbf{Y})$ .
- 6: end while

# Algorithm: A Little Lesson from History

Comparison from chronological development of algorithms for solving the PCP problem: **the older the algorithm, the more efficient!** 

GOOD NEWS: Scalable first-order gradient-descent algorithms:

- Proximal Gradient [Osher, Mao, Dong, Yin '09, Wright et. al.'09, Cai et. al.'09].
- Accelerated Proximal Gradient [Nesterov '83, Beck and Teboulle '09]:
- Augmented Lagrange Multiplier [Hestenes '69, Powell '69]:
- · Alternating Direction Method of Multipliers [Gabay and Mercier '76].

For a 1000x1000 matrix of rank 50, with 10% (100,000) entries randomly corrupted: min  $\|A\|_* + \lambda \|E\|_1$  subj A + E = D.

Algorithms	Accuracy	Rank	E  _0	# iterations	time (sec)
IT	5.99e-006	50	101,268	8,550	119,370.3
DUAL	8.65e-006	50	100,024	822	1,855.4
APG	5.85e-006	50	100,347	134	1,468.9
APG <sub>P</sub>	5.91e-006	50	100,347	134	82.7

## When is decomposition possible?

Identifiability issue: a matrix might be simultaneously low-rank and sparse!

Nonzero entries of sparse component need to be spread out

— This lecture: assume locations of the nonzero entries are random

## When is decomposition possible?

Identifiability issue: a matrix might be simultaneously low-rank and sparse!

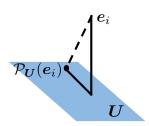

The low-rank component needs to be incoherent

## Low-rank component: incoherence

#### Definition

Incoherence parameter  $\mu_1$  of  $m{L}_o = m{U} m{\Sigma} m{V}^*$  is the smallest quantity s.t.

$$\max_i \|\boldsymbol{e}_i^*\boldsymbol{U}\|_2^2 \leq \frac{\mu_1 r}{n} \quad \text{and} \quad \max_i \|\boldsymbol{e}_i^*\boldsymbol{V}\|_2^2 \leq \frac{\mu_1 r}{n}$$

## Low-rank component: joint coherence

#### Definition (Joint coherence)

Joint coherence parameter  $\mu_2$  of  $m{L}_o = m{U} m{\Sigma} m{V}^*$  is the smallest quantity s.t.

$$\|\boldsymbol{U}\boldsymbol{V}^*\|_{\infty} \le \sqrt{\frac{\mu_2 r}{n^2}}$$

This prevents  $UV^*$  from being too peaky

•  $\mu_1 \le \mu_2 \le \mu_1^2 r$ , since

$$|(\boldsymbol{U}\boldsymbol{V}^*)_{ij}| = |\boldsymbol{e}_i^{\top}\boldsymbol{U}\boldsymbol{V}_j^*| \le \|\boldsymbol{e}_i^{\top}\boldsymbol{U}\|_2 \cdot \|\boldsymbol{V}_j^*\|_2 \le \frac{\mu_1 r}{n}$$

$$\| \boldsymbol{U} \boldsymbol{V}^* \|_{\infty}^2 \geq \frac{\| \boldsymbol{U} \boldsymbol{V}^* \boldsymbol{e}_j \|_{\mathrm{F}}^2}{n} = \frac{\| \boldsymbol{V}_j^* \|_2^2}{n} = \frac{\mu_1 r}{n^2} \; (\text{suppose } \| \boldsymbol{V}_j^* \|_2^2 = \frac{\mu_1 r}{n})$$

In the book we have set  $\mu_1 = \mu_2 = \nu$ .

# Theoretical guarantee

## Theorem (Candès, Li, Ma, Wright '11)

- $\operatorname{rank}(\boldsymbol{L}) \lesssim \frac{n}{\max\{\mu_1,\mu_2\}\log^2 n}$ ;
- Nonzero entries of S are randomly located, and  $||S||_0 \le \rho_s n^2$  for some constant  $\rho_s > 0$  (e.g.  $\rho_s = 0.2$ ).

Then PCP with  $\lambda = 1/\sqrt{n}$  is exact with high prob.

- rank(L) can be quite high (up to n/polylog(n))
- Parameter free:  $\lambda = 1/\sqrt{n}$
- Ability to correct gross error:  $\|S\|_0 \asymp n^2$
- ullet Sparse component  $oldsymbol{S}$  can have arbitrary magnitudes / signs!

# Geometry

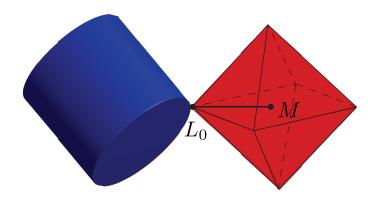

Fig. credit: Candès'14

#### Dense error correction

## Theorem (Ganesh, Wright, Li, Candès, Ma'10, Chen, Jalali, Sanghavi, Caramanis'13)

- $\operatorname{rank}(\boldsymbol{L}) \lesssim \frac{n}{\max\{\mu_1, \mu_2\} \log^2 n}$ ;
- Nonzero entries of S are randomly located, have random sign, and  $||S||_0 = \rho_s n^2$ .

Then PCP with  $\lambda symp \sqrt{rac{1ho_s}{
ho_s n}}$  succeeds with high prob., provided that

$$\underbrace{1 - \rho_s}_{\text{non-corruption rate}} \gtrsim \sqrt{\frac{\max\{\mu_1, \mu_2\}r \operatorname{polylog}(n)}{n}}$$

 When additive corruptions have random signs, PCP works even when a dominant fraction of the entries are corrupted

# Is joint coherence needed?

- Matrix completion: does not need  $\mu_2$
- Robust PCA: so far we need  $\mu_2$

**Question:** Can we recover L with rank up to  $\frac{n}{\mu_1 \mathrm{polylog}(n)}$  (rather than  $\frac{n}{\max\{\mu_1,\mu_2\}\mathrm{polylog}(n)}$ )?

Answer: No

## Planted clique problem

**Setup:** a graph  $\mathcal G$  of n nodes generated as follows

- 1. connect each pair of nodes independently with prob. 0.5
- 2. pick  $n_0$  nodes and make them a clique (fully connected)

**Goal:** find the hidden clique from  $\mathcal G$ 

Information theoretically, one can recover the clique if  $n_0 > 2\log_2 n$ 

# Conjecture on computational barrier

**Conjecture:**  $\forall$  constant  $\epsilon > 0$ , if  $n_0 \leq n^{0.5 - \epsilon}$ , then no tractable algorithm can find the clique from  $\mathcal{G}$  with prob. 1 - o(1)

— often used as a hardness assumption

#### Lemma

If there is an algorithm that allows recovery of any L from Y with  $\mathrm{rank}(L) \leq \frac{n}{\mu_1 polylog(n)}$ , then the above conjecture is violated.

#### Proof of Lemma 6

Suppose  $oldsymbol{L}$  is the true adjacency matrix,

$$L_{i,j} = \begin{cases} 1, & \text{if } i,j \text{ are both in the clique} \\ 0, & \text{else} \end{cases}$$

Let A be the adjacency matrix of  $\mathcal{G}$ , and generate Y s.t.

$$M_{i,j} = egin{cases} A_{i,j}, & \text{with prob. } 2/3 \\ 0, & \text{else} \end{cases}$$

Therefore, one can write

$$oldsymbol{Y} = oldsymbol{L} + oldsymbol{\underbrace{Y-L}}$$
 each entry is nonzero w.p.  $1/3$ 

#### Proof of Lemma 6

Note that

$$\mu_1 = \frac{n}{n_0} \qquad \text{and} \qquad \mu_2 = \frac{n^2}{n_0^2}$$

If there is an algorithm that can recover any L of rank  $\frac{n}{\mu_1\mathsf{polylog}(n)}$  from M, then

$$\operatorname{rank}(\boldsymbol{L}) = 1 \leq \frac{n}{\mu_1 \operatorname{polylog}(n)} \quad \Longleftrightarrow \quad n_0 \geq \operatorname{polylog}(n)$$

But this contradicts the conjecture (which claims computational infeasibility to recover L unless  $n_0 \geq n^{0.5-o(1)}$ )
